

# A Non-wellfounded, Labelled Proof System for Propositional Dynamic Logic

---

Simon Docherty, University College London

Reuben N. S. Rowe, Royal Holloway University of London

TABLEAUX 2019

2<sup>nd</sup>–5<sup>th</sup> September 2019, Middlesex University, London, UK

# What is Dynamic Logic?

Dynamic Logic was introduced by Pratt (1976)

- Reasoning about program executions (i.e. their **dynamics**)
- A **modal** logic (programs are modal operators)

$$x \geq 3 \rightarrow [x := x + 1](x \geq 4)$$

# What is Dynamic Logic?

Dynamic Logic was introduced by Pratt (1976)

- Reasoning about program executions (i.e. their **dynamics**)
- A **modal** logic (programs are modal operators)

$$x \geq 3 \rightarrow [x := x + 1](x \geq 4)$$

Intuitively, for a program  $p$  and assertion  $\varphi$ :

$[p]\varphi$  means  $\varphi$  holds after *all* (terminating) executions of  $p$

$\langle p \rangle \varphi$  means there is *some* execution of  $p$  after which  $\varphi$  holds

# The Language of Programs

Programs are constructed from:

- A set of basic programs (e.g.  $x := x + 1$ )
- Sequential composition  $p ; q$
- Non-deterministic choice  $p \cup q$
- Iteration  $p^*$

# The Language of Programs

Programs are constructed from:

- A set of basic programs (e.g.  $x := x + 1$ )
- Sequential composition  $p ; q$
- Non-deterministic choice  $p \cup q$
- Iteration  $p^*$
- For any formula  $\varphi$ , the **test**  $\varphi?$  is a program

# The Language of Programs

Programs are constructed from:

- A set of basic programs (e.g.  $x := x + 1$ )
- Sequential composition  $p ; q$
- Non-deterministic choice  $p \cup q$
- Iteration  $p^*$
- For any formula  $\varphi$ , the **test**  $\varphi?$  is a program

So, programs form a Kleene Algebra (with tests)

# The Language of Programs

Programs are constructed from:

- A set of basic programs (e.g.  $x := x + 1$ )
- Sequential composition  $p ; q$
- Non-deterministic choice  $p \cup q$
- Iteration  $p^*$
- For any formula  $\varphi$ , the **test**  $\varphi?$  is a program

So, programs form a Kleene Algebra (with tests)

- Various extensions: converse  $p^-$ , intersection  $p \cap q$ , etc.

## Relational (Kripke) Semantics of Dynamic Logic

Basic programs are accessibility relations on (memory) states  $s \in \mathcal{S}$

$$[\![x := x + 1]\!] = \{(x \mapsto 0, x \mapsto 1), (x \mapsto 1, x \mapsto 2), \dots\}$$

## Relational (Kripke) Semantics of Dynamic Logic

Basic programs are accessibility relations on (memory) states  $s \in \mathcal{S}$

$$\llbracket x := x + 1 \rrbracket = \{(x \mapsto 0, x \mapsto 1), (x \mapsto 1, x \mapsto 2), \dots\}$$

Formulas are interpreted as sets of states

$$\llbracket \langle p \rangle \varphi \rrbracket = \{s \mid (s, s') \in \llbracket p \rrbracket \wedge s' \in \llbracket \varphi \rrbracket\}$$

$$\llbracket [p] \varphi \rrbracket = \neg \llbracket \langle p \rangle \neg \varphi \rrbracket = \mathcal{S} \setminus \{s \mid (s, s') \in \llbracket p \rrbracket \wedge s' \in \mathcal{S} \setminus \llbracket \varphi \rrbracket\}$$

# Relational (Kripke) Semantics of Dynamic Logic

Basic programs are accessibility relations on (memory) states  $s \in \mathcal{S}$

$$\llbracket x := x + 1 \rrbracket = \{(x \mapsto 0, x \mapsto 1), (x \mapsto 1, x \mapsto 2), \dots\}$$

Formulas are interpreted as sets of states

$$\llbracket \langle p \rangle \varphi \rrbracket = \{s \mid (s, s') \in \llbracket p \rrbracket \wedge s' \in \llbracket \varphi \rrbracket\}$$

$$\llbracket [p] \varphi \rrbracket = \neg \llbracket \langle p \rangle \neg \varphi \rrbracket = \mathcal{S} \setminus \{s \mid (s, s') \in \llbracket p \rrbracket \wedge s' \in \mathcal{S} \setminus \llbracket \varphi \rrbracket\}$$

Relational interpretation of the program algebra is standard

$$\llbracket p ; q \rrbracket = \llbracket p \rrbracket \circ \llbracket q \rrbracket \quad \llbracket p \cup q \rrbracket = \llbracket p \rrbracket \cup \llbracket q \rrbracket \quad \llbracket p^* \rrbracket = \bigcup_{n \geq 0} \llbracket p \rrbracket^n$$

# Relational (Kripke) Semantics of Dynamic Logic

Basic programs are accessibility relations on (memory) states  $s \in \mathcal{S}$

$$\llbracket x := x + 1 \rrbracket = \{(x \mapsto 0, x \mapsto 1), (x \mapsto 1, x \mapsto 2), \dots\}$$

Formulas are interpreted as sets of states

$$\llbracket \langle p \rangle \varphi \rrbracket = \{s \mid (s, s') \in \llbracket p \rrbracket \wedge s' \in \llbracket \varphi \rrbracket\}$$

$$\llbracket [p] \varphi \rrbracket = \neg \llbracket \langle p \rangle \neg \varphi \rrbracket = \mathcal{S} \setminus \{s \mid (s, s') \in \llbracket p \rrbracket \wedge s' \in \mathcal{S} \setminus \llbracket \varphi \rrbracket\}$$

Relational interpretation of the program algebra is standard

$$\llbracket p ; q \rrbracket = \llbracket p \rrbracket \circ \llbracket q \rrbracket \quad \llbracket p \cup q \rrbracket = \llbracket p \rrbracket \cup \llbracket q \rrbracket \quad \llbracket p^* \rrbracket = \bigcup_{n \geq 0} \llbracket p \rrbracket^n$$

But tests introduce a mutual recursion:  $\llbracket \varphi ? \rrbracket = \{(s, s) \mid s \in \llbracket \varphi \rrbracket\}$

# The Influence of Dynamic Logic

Lots of variants and extensions:

- Games (Parikh, '83)
- Natural language (Groenendijk & Stokhof, '91)
- Knowledge representation (De Giacomo & Lenzarini, '94)
- XML (Afanasiev Et Al, 2005)
- Cyber-physical systems (Platzer, 2008)
- Epistemic reasoning for agents (Patrick Girard Et Al, 2012)
- etc.

## What is Propositional Dynamic Logic?

Fischer & Ladner (1979) first studied the **propositional** fragment

- Only abstract propositional programs
- No quantification

# What is Propositional Dynamic Logic?

Fischer & Ladner (1979) first studied the **propositional** fragment

- Only abstract propositional programs
- No quantification

PDL is the logic of (regular) programs

$$[\alpha^*]((\varphi \rightarrow [\alpha]\neg\varphi) \wedge (\neg\varphi \rightarrow [\alpha]\varphi)) \leftrightarrow [(\alpha ; \alpha)^*]\varphi \vee [(\alpha ; \alpha)^*]\neg\varphi$$

# What is Propositional Dynamic Logic?

Fischer & Ladner (1979) first studied the **propositional** fragment

- Only abstract propositional programs
- No quantification

PDL is the logic of (regular) programs

$$[\alpha^*]((\varphi \rightarrow [\alpha]\neg\varphi) \wedge (\neg\varphi \rightarrow [\alpha]\varphi)) \leftrightarrow [(\alpha ; \alpha)^*]\varphi \vee [(\alpha ; \alpha)^*]\neg\varphi$$

**if**  $\varphi$  **then**  $\alpha$  **else**  $\beta \stackrel{\text{def}}{=} (\varphi? ; \alpha) \cup (\neg\varphi? ; \beta)$

**while**  $\varphi$  **do**  $\alpha \stackrel{\text{def}}{=} (\varphi? ; \alpha)^* ; \neg\varphi?$

# PDL: Main Properties and Results

- Small model property
- Satisfiability EXPTIME-complete
- Finitely axiomatisable

(K)	$\vdash [\alpha](\varphi \rightarrow \psi) \rightarrow ([\alpha]\varphi \rightarrow [\alpha]\psi)$	(Test)	$\vdash [\psi?]\varphi \leftrightarrow (\psi \rightarrow \varphi)$
(Distributivity)	$\vdash [\alpha](\varphi \wedge \psi) \leftrightarrow ([\alpha]\varphi \wedge [\alpha]\psi)$	(Fixed Point)	$\vdash \varphi \wedge [\alpha][\alpha^*]\varphi \leftrightarrow [\alpha^*]\varphi$
(Choice)	$\vdash [\alpha \cup \beta]\varphi \leftrightarrow [\alpha]\varphi \wedge [\beta]\varphi$	(Induction)	$\vdash \varphi \wedge [\alpha^*](\varphi \rightarrow [\alpha]\varphi) \rightarrow [\alpha^*]\varphi$
(Composition)	$\vdash [\alpha ; \beta]\varphi \leftrightarrow [\alpha][\beta]\varphi$	(Necessitation)	from $\vdash \varphi$ infer $\vdash [\alpha]\varphi$

Dual axioms for  $\langle \alpha \rangle$  (if taken as a primitive)

# PDL: Main Properties and Results

- Small model property
- Satisfiability EXPTIME-complete
- Finitely axiomatisable

(K)	$\vdash [\alpha](\varphi \rightarrow \psi) \rightarrow ([\alpha]\varphi \rightarrow [\alpha]\psi)$	(Test)	$\vdash [\psi?]\varphi \leftrightarrow (\psi \rightarrow \varphi)$
(Distributivity)	$\vdash [\alpha](\varphi \wedge \psi) \leftrightarrow ([\alpha]\varphi \wedge [\alpha]\psi)$	(Fixed Point)	$\vdash \varphi \wedge [\alpha][\alpha^*]\varphi \leftrightarrow [\alpha^*]\varphi$

Dual axioms for  $\langle \alpha \rangle$  (if taken as a primitive)

- But not compact       $\{\neg\varphi, [\alpha]\neg\varphi, [\alpha ; \alpha]\neg\varphi, [\alpha ; \alpha ; \alpha]\neg\varphi, \dots\} \not\models \langle \alpha^* \rangle \varphi$

# Proof Systems for PDL

Tableaux-based systems:

- De Giacomo & Massacci, 2000
- Goré & Widmann, 2009

Sequent-based with  $\omega$ -rules/infinite contexts:

- Renardel de Lavalette Et Al, 2008
- Hill & Poggiolesi, 2010
- Fritella Et Al, 2014

## Our Goal: A Satisfactory Proof Theory

A robust, structural proof theory for PDL and PDL-type logics

- Analytic and finitary (i.e. automatable!)
- Uniform, modular and extensible

# Our Goal: A Satisfactory Proof Theory

A robust, structural proof theory for PDL and PDL-type logics

- Analytic and finitary (i.e. automatable!)
- Uniform, modular and extensible

We combine two methodologies

- Labelled sequent calculus
- Non-wellfounded proof theory

# Why Labelled Sequent Calculus?

Modularly capture a range of modal logics (Negri, 2005) using:

- Labelled formulas  $x : \varphi$  and relational statements  $x R y$
- Proof rules expressing the meaning of modalities

$$\frac{y : \varphi, x : \square\varphi, x R y, \Gamma \Rightarrow \Delta}{x : \square\varphi, x R y, \Gamma \Rightarrow \Delta}$$

$$\frac{x R y, \Gamma \Rightarrow \Delta, y : \varphi}{\Gamma \Rightarrow \Delta, x : \square\varphi} \text{ (y fresh)}$$

- Proof rules characterising different (geometric) frame properties, e.g.

$$\text{(symm): } \frac{y R x, x R y, \Gamma \Rightarrow \Delta}{x R y, \Gamma \Rightarrow \Delta}$$

$$\text{(trans): } \frac{x R z, x R y, y R z, \Gamma \Rightarrow \Delta}{x R y, y R z, \Gamma \Rightarrow \Delta}$$

- Even possible to capture some non-modally definable frame properties

## Why Non-wellfounded Proofs?

They allow us to tame (inductive) infinitary behaviour

- Allow derivations to be infinitely **tall** (vs. wide) – not generally sound!
- Distinguish ‘good’ derivations with a global trace condition
- Restrict to (finitely representable) **cyclic** proofs

# Why Non-wellfounded Proofs?

They allow us to tame (inductive) infinitary behaviour

- Allow derivations to be infinitely **tall** (vs. wide) – not generally sound!
- Distinguish ‘good’ derivations with a global trace condition
- Restrict to (finitely representable) **cyclic** proofs

Examples of non-wellfounded proof theories include:

- FOL + Inductive Definitions (Brotherston & Simpson)
- FOL over Herbrand models (Cohen, R, Zohar)
- Linear Logic with fixed points  
(Fortier & Santocanale, Baelde/Saurin/Doumane/Nollet/Tasson)
- Kleene/Action Algebra (Das & Pous)

# Our Non-wellfounded, Labelled Sequent Calculus for PDL

- Relational statements  $x R_a y$  refer to atomic programs  $a$
- Rules for atomic modalities à la Negri

$$(\square L): \frac{y : \varphi, \Gamma \Rightarrow \Delta}{x : [a]\varphi, x R_a y, \Gamma \Rightarrow \Delta}$$

$$(\square R): \frac{x R_a y, \Gamma \Rightarrow \Delta, y : \varphi}{\Gamma \Rightarrow \Delta, x : [a]\varphi} \text{ (y fresh)}$$

# Our Non-wellfounded, Labelled Sequent Calculus for PDL

- Relational statements  $x R_a y$  refer to atomic programs  $a$
- Rules for atomic modalities à la Negri

$$(\square L): \frac{y : \varphi, \Gamma \Rightarrow \Delta}{x : [a]\varphi, x R_a y, \Gamma \Rightarrow \Delta}$$

$$(\square R): \frac{x R_a y, \Gamma \Rightarrow \Delta, y : \varphi}{\Gamma \Rightarrow \Delta, x : [a]\varphi} \text{ (y fresh)}$$

- Decompose non-atomic modalities as per semantics, e.g.

$$(\cup L): \frac{x : [\alpha]\varphi, x : [\beta]\varphi, \Gamma \Rightarrow \Delta}{x : [\alpha \cup \beta]\varphi, \Gamma \Rightarrow \Delta}$$

$$(\cup R): \frac{\Gamma \Rightarrow \Delta, x : [\alpha]\varphi \quad \Gamma \Rightarrow \Delta, x : [\beta]\varphi}{\Gamma \Rightarrow \Delta, x : [\alpha \cup \beta]\varphi}$$

# Our Non-wellfounded, Labelled Sequent Calculus for PDL

- Relational statements  $x R_a y$  refer to atomic programs  $a$
- Rules for atomic modalities à la Negri

$$(\square L): \frac{y : \varphi, \Gamma \Rightarrow \Delta}{x : [a]\varphi, x R_a y, \Gamma \Rightarrow \Delta}$$

$$(\square R): \frac{x R_a y, \Gamma \Rightarrow \Delta, y : \varphi}{\Gamma \Rightarrow \Delta, x : [a]\varphi} \quad (\text{y fresh})$$

- Decompose non-atomic modalities as per semantics, e.g.

$$(\cup L): \frac{x : [\alpha]\varphi, x : [\beta]\varphi, \Gamma \Rightarrow \Delta}{x : [\alpha \cup \beta]\varphi, \Gamma \Rightarrow \Delta}$$

$$(\cup R): \frac{\Gamma \Rightarrow \Delta, x : [\alpha]\varphi \quad \Gamma \Rightarrow \Delta, x : [\beta]\varphi}{\Gamma \Rightarrow \Delta, x : [\alpha \cup \beta]\varphi}$$

- Rules for iteration express its nature as a fixed point

$$(*L): \frac{x : \varphi, x : [\alpha][\alpha^*]\varphi, \Gamma \Rightarrow \Delta}{x : [\alpha^*]\varphi, \Gamma \Rightarrow \Delta}$$

$$(*R): \frac{\Gamma \Rightarrow \Delta, x : \varphi \quad \Gamma \Rightarrow \Delta, x : [\alpha][\alpha^*]\varphi}{\Gamma \Rightarrow \Delta, x : [\alpha^*]\varphi}$$

# A ‘Bad’ Non-wellfounded Derivation

$$\frac{\vdots}{\Rightarrow x : [\alpha^*]\varphi, x : [\alpha^*]\varphi} \text{ (CR)} \quad \frac{\vdots}{\Rightarrow x : [\alpha^*]\varphi, x : [\alpha^*]\varphi} \text{ (CR)}$$
$$\frac{\vdots}{\Rightarrow x : [\alpha^*]\varphi} \text{ (WR)} \quad \frac{\vdots}{\Rightarrow x : [\alpha^*]\varphi} \text{ (WR)}$$
$$\frac{\vdots}{\Rightarrow x : [\alpha^*]\varphi, x : \varphi} \quad \frac{\vdots}{\Rightarrow x : [\alpha^*]\varphi, x : [\alpha][\alpha^*]\varphi} \text{ (*R)}$$
$$\frac{\vdots}{\Rightarrow x : [\alpha^*]\varphi, x : [\alpha^*]\varphi} \text{ (CR)}$$
$$\frac{\vdots}{\Rightarrow x : [\alpha^*]\varphi}$$

# 'Good' Proofs: The Global Trace Condition

We trace (possibly nested) modalities on the right-hand side

- They must be unfolded infinitely often along infinite paths

$$\frac{\frac{\frac{\frac{x : \varphi \Rightarrow x : \varphi}{x : \varphi, x : [a^*][a^*]\varphi \Rightarrow x : \varphi} (*L)}{x : [a^*]\varphi \Rightarrow x : \varphi} (\text{WL})}{\frac{x : [a^*]\varphi \Rightarrow x : [a^{**}]\varphi}{x : [a^*]\varphi \Rightarrow x : [a^*][a^{**}]\varphi} (\text{Ax})} (\text{Subst})}{\frac{y : [a^*]\varphi \Rightarrow y : [a^*][a^{**}]\varphi}{x : \varphi, y : [a^*]\varphi \Rightarrow y : [a^*][a^{**}]\varphi} (\text{WL})} (\text{WL})}$$
$$\frac{x R_a y, x : \varphi, x : [a][a^*]\varphi \Rightarrow y : [a^*][a^{**}]\varphi}{x : \varphi, x : [a][a^*]\varphi \Rightarrow x : [a][a^*][a^{**}]\varphi} (\square L)$$
$$\frac{x : \varphi, x : [a][a^*]\varphi \Rightarrow x : [a][a^*][a^{**}]\varphi}{x : [a^*]\varphi \Rightarrow x : [a][a^*][a^{**}]\varphi} (*R)$$
$$\frac{x : [a^*]\varphi \Rightarrow x : [a][a^*][a^{**}]\varphi}{x : [a^*]\varphi \Rightarrow x : [a^*][a^{**}]\varphi} (*R)$$

## Theorem

*If  $\varphi$  is a PDL theorem, there is a cyclic proof deriving  $\Rightarrow x : \varphi$*

# Proof Search for Test-free sequents

We propose the following proof-search strategy:

- Apply (invertible) logical rules as much as possible
  - But do not allow traces to progress more than once
  - For test-free sequents, this terminates
- Close open leaves with axioms where possible
- Apply a series of validity-preserving weakenings
- Repeat process for any remaining open leaves

All formulas that appear are in the Fischer-Ladner closure of the end sequent

## Conjecture

*The number of distinct labels appearing in a sequent is bounded*

## Future Work

- Prove cut-free regular completeness results (also for tests?)
- Demonstrate capture of different frame conditions
- Incorporate additional constructs in the program algebra
  - Converse, Intersection
- Extend to capture other modal fixpoints (temporal, common knowledge)
- Derive interpolation results from the proof theory
  - cf. Cyclic system and Lyndon interpolation for GL (Shamkanov, 2014)
